A*

Simulated
annealing

Beam search

- ▶ Without some guidance: average case is likely to be exponential
- ▶ Can we do better by using *knowledge* to
 - ▶ prioritize nodes to expand?
 - ▶ prune some paths entirely?

Heuristic search

- ▶ Use *heuristics* to search smarter
- ▶ Heuristic: “rule of thumb”, estimate, guess about
 - ▶ search space topology
 - ▶ problem domain property
 - ▶ problem-solving process itself
- ▶ *Defeasible*
- ▶ Should be easy to calculate

Uniformed search

Heuristic search

Hill-climbing

Greedy search

A*

Iterative
Deepening A*

Memory-bounded
A*

Simulated
annealing

Beam search

- ▶ *Heuristic function* maps state \rightarrow worth
- ▶ Apply heuristic to child states
- ▶ Expand most desirable state first

Uniformed search

Heuristic search

Hill-climbing

Greedy search

A*

Iterative
Deepening A*

Memory-bounded
A*

Simulated
annealing

Beam search

- ▶ Differ in kind of information/heuristics available
 - ▶ Local information:
 - ▶ How good is *this* state?
 - ▶ How good are the *next* states
 - ▶ Global information:
 - ▶ How close is this state/next state(s) compared to goal?
 - ▶ How good is the path this/next states are on?
- ▶ Optimality or even completeness may not be guaranteed

Uninformed search

Heuristic search

Hill-climbing

Greedy search

A*

Iterative
Deepening A*

Memory-bounded
A*

Simulated
annealing

Beam search

- ▶ Idea: pick best node to expand next
- ▶ Recall R&N's general algorithm for search:

function GENERAL-SEARCH(*problem*, QUEUING-FN) **returns** a solution, or failure

nodes \leftarrow MAKE-QUEUE(MAKE-NODE(INITIAL-STATE[*problem*]))

loop do

if *nodes* is empty **then return** failure

node \leftarrow REMOVE-FRONT(*nodes*)

if GOAL-TEST[*problem*] applied to STATE(*node*) succeeds **then return** *node*

nodes \leftarrow QUEUING-FN(*nodes*, EXPAND(*node*, OPERATORS[*problem*]))

end

- ▶ Have Queuing-Fn pick *best* node picked first based on heuristic function

Hill-climbing

Greedy search

A*

Iterative
Deepening A*

Memory-bounded
A*

Simulated
annealing

Beam search

Hill-climbing

- ▶ Simple, purely local best-first search
- ▶ Analogy: real hill-climbing
 - ▶ When path branches, choose direction that increased altitude
 - ▶ May not be good: but best with available information
- ▶ Sometimes “up” is “down”: want lowest cost, e.g.
- ▶ *Gradient descent* (← neural network’s backprop)

Uninformed search

Heuristic search

Hill-climbing

Greedy search

A*

Iterative
Deepening A*

Memory-bounded
A*

Simulated
annealing

Beam search

- ▶ Let $h(s_i)$ = heuristic function, s = current state
- ▶ *Simple hill climbing*: if $h(s_i) > h(s)$, choose s_i
- ▶ *Steepest-ascent hill-climbing*: choose *best* s_i that is better than s :
Choose $s_m = \operatorname{argmax}(h(s_i))$ if $h(s_m) > h(s)$

Which to choose?

- ▶ Steepest-ascent: maybe quicker to goal
- ▶ Simple may be quicker to do: e.g., large # of children, expensive heuristic function

Heuristic Search

A*

Simulated
annealing

Beam search

Save history or not?

Heuristic Search

- ▶ No history:
 - ▶ Reduce space complexity
 - ▶ But could repeat states if poor/uncertain heuristics → infinite loop
 - ▶ *Local minima* problem
- ▶ Save history:
 - ▶ If local minimum \neq goal, can *backtrack*
 - ▶ Doesn't solve local minima problem in general...
 - ▶ ... e.g., "go as far east as possible"

Beam search

Escaping local minima

Heuristic Search

- ▶ Possible solution: *backtrack*
- ▶ Implementation: DFS, but order expansion by child cost
- ▶ But what if this is the initial state:

- ▶ Also, what if relative goal, e.g., “go East as far as you can”?

Uniformed search

Heuristic search

Iterative
Deepening A*

Memory-bounded
A*

Simulated
annealing

Beam search

Problem: Ridges

Heuristic Search

- ▶ Have ≥ 2 axes, continuous space
- ▶ Heuristic function looks something like:

- ▶ Progress if stepping in one dimension: slow, zig-zag
- ▶ Maybe can't make a single move to a better position
- ▶ Possible solution: try several moves in a row

Uniformed search

Heuristic search

Hill-climbing

Greedy search

Greedy search

A*

Iterative
Deepening A*

Memory-bounded
A*

Simulated
annealing

Beam search

Hill-climbing advantages

Heuristic Search

- ▶ Good when we want to quickly find reasonable solution
 - ▶ Premise: local optimality \Rightarrow global optimality
 - ▶ If local heuristic always accurate \Rightarrow goal
 - ▶ May be the best we can do without *some* global information
- ▶ Can be used to search real world
- ▶ May sometimes get heuristic for free
 - ▶ If side-effect of checking for goal
 - ▶ E.g., if goal is to be close to x , then get distance during goal check

Heuristic search

Hill-climbing

Greedy search

A*

Iterative
Deepening A*

Memory-bounded
A*

Simulated
annealing

Beam search

- ▶ No guarantee of optimality!
- ▶ Local character of heuristics \Rightarrow plateau, ridge, minima problems
- ▶ Hard to get started in some problems if all choices look the same
 - ▶ Example: Robot in Boardman, wants to get to downtown Orono
 - ▶ Huge number of possible “next states”
 - ▶ All about the same in terms of distance from downtown

Started from the bottom, now we're here...

—A.D. Graham

*Always gonna be a uphill battle
Sometimes I'm gonna have to lose
Ain't about how fast I get there,
Ain't about what's waiting on the other side
It's the climb*

—M. Cyrus

Deepening A*

Memory-bounded
A*

Simulated
annealing

Beam search

Greedy search

- ▶ Hill-climbing is one type of *greedy* search:
 - ▶ Pick better/best next node
 - ▶ HC is local, however
- ▶ Can also have non-local greedy search
- ▶ Choose best node from *frontier* – as in uniform-cost search
 - ▶ “Best” now incorporates heuristic
 - ▶ $h(s)$ estimates distance to goal

Can We Do Better?

- ▶ Uniform-cost (branch-and-bound): complete, optimal; no heuristics
- ▶ Greedy search: usually quick to zero in on goal; not guaranteed to be optimal
- ▶ Why not combine them?

Beam search

- ▶ Greedy with respect to estimated *total path cost*
- ▶ Given: problem with start S and goal G
- ▶ Let $f(i) = g(i) + h(i)$ be best-cost path from $S \rightarrow G$ through i
 - ▶ $g(i)$ = cost of best path $S \rightarrow i$
 - ▶ $h(i)$ = cost of best path $i \rightarrow G$
- ▶ Can know $g(i)$
- ▶ Estimate $h(i)$ by $h'(i)$ (also: $h^*(i)$): a heuristic function
- ▶ $f'(i) = g(i) + h'(i)$ = estimate of best cost path through i
- ▶ From the frontier: pick node with minimum f'

- ▶ Could use R&N's

`Best-First-Search(problem, g+h\prime{ })`

- ▶ May be easier to understand as standard algorithm
- ▶ Sketch:
 - ▶ Put start on a queue of open nodes
 - ▶ At each point:
 - ▶ Select the open (frontier) node with the best $f'(i)$
 - ▶ If none, fail; if goal, success.
 - ▶ Otherwise, update $f'(i)$ for the children, add them to queue
 - ▶ Hopefully f' is a better estimate of f as search progresses

function $A^*(p)$

Input: a problem p

Returns: path to solution or nil if none

Let Open, Closed be empty lists

Let Current = a search node

Current.state = Start(p)

Current.f = h(Start), Current.g = 0

Add Current to Open

while Open is non-empty **do**

 Current = node on Open with lowest f value

 Remove Current from Open, put on Closed

if Current.state = Goal(p) **then**

 Compute path to Current, return path

Admissibility of A*

Heuristic Search

- ▶ Suppose A* selects a goal node G from Open
- ▶ $\Rightarrow \forall i \in \text{Open}, f'(G) \leq f'(i)$
- ▶ Suppose $\forall i \in \text{Open}, h'(i) \leq h(i)$
 - ▶ $\Rightarrow h'$ is an *underestimating* heuristic
 - ▶ $\Rightarrow f'$ also underestimates f for all nodes
- ▶ Nodes really represent *paths* to goal through a state
- ▶ $f'(G) = f(G)$ since we are at goal
- ▶ Cost of path to G \leq all other estimated costs...
- ▶ ...and estimated costs \leq actual costs...
- ▶ \therefore G is optimal path
- ▶ \therefore A* is admissible with underestimating heuristics

Overestimating heuristics

Heuristic Search

- ▶ We consider $h' \leq h$ to be underestimating heuristic
- ▶ What if sometimes $h' > h$?
- ▶ Suppose G , representing a path to goal, is selected from Open
 - ▶ $f(g) \leq f'(i), \forall i \in \text{Open}$
 - ▶ But some $f'(i) > f(i)$
 - ▶ \therefore possible: $f(i) < f(G) \Rightarrow G$ not optimal path
- ▶ Also:
 - ▶ Extra work may be done during search
 - ▶ Select node j , but possible $f(i) < f(j)$

How to find heuristics?

Heuristic Search

- ▶ *Relax* problem by taking away some condition in problem statement
- ▶ Exact solution to relaxed problem often good heuristic
- ▶ E.g., in Robot World:
 - ▶ Problem: Move from S to G using Manhattan moves and avoiding obstacles
 - ▶ Relaxed 1: Move from S to G using Manhattan moves.
 - ▶ Relaxed 2: Move from S to G

► *Effective branching factor:*

- Suppose expand N nodes for depth d solution
- In a balanced tree, what would have been branching factor?
- No closed-form solution, but can estimate b^*
 - $b^* \approx 2^{\log N/d}$ – or
 - $b^* \approx N^{1/d}$
- E.g.:
 - Expand $N = 1024$ nodes, depth $d = 10$: $b^* \approx 2$
 - Expand $N = 1000$ nodes, depth $d = 5$: $b^* \approx 4$;
 $4^5 = 1024$

- Heuristic h_1 is better h_2 if $b_1^* < b_2^*$ for all nodes
- Ideally: b^* close to 1

Memory-bounded
A*

Simulated
annealing

Beam search

Properties of A*

Heuristic Search

- ▶ A* is *optimally efficient*: for any heuristic function, no other optimal algorithm is guaranteed to expand fewer nodes
- ▶ If A^*_1 uses h'_1 and A^*_2 uses h'_2 and $h'_1(n) > h'_2(n)$ for all n , then A^*_2 expands *at least* every node that A^*_1 does
- ▶ Time complexity: still $\mathcal{O}(b^d)$ in worst case
- ▶ Space complexity: Poor – keeps all expanded nodes in memory!

Deepening A*

Memory-bounded
A*

Simulated
annealing

Beam search

- ▶ Time depends on properties of h'
 - ▶ If h' has large *grain size*, then search quite a bit of the tree each DFS call
 - ▶ Small grain size: DFS may be called many times – worst case, once per expanded node
 - ▶ if A* expands a nodes, IDA* in this case expands $1 + 2 + \dots + a = a^2$ nodes
 - ▶ worst case: $\mathcal{O}((b^d)^2) = \mathcal{O}(b^{2d})$
 - ▶ Example
 - ▶ Can ameliorate this by forcing granularity to be coarse
 - ▶ Increase f' contour by ϵ each time
 - ▶ Solution could be as much as ϵ sub-optimal
 - ▶ *ϵ -admissibility*
 - ▶ Example

- ▶ Can we do better with respect to space?
- ▶ Simple memory-bounded A*
 - ▶ Uses whatever memory you give it
 - ▶ If enough memory to store a solution \Rightarrow complete
 - ▶ If enough to store optimal solution \Rightarrow optimal
 - ▶ If not, will return best solution that will fit in memory
- ▶ Idea:
 - ▶ Proceed like A*, but when bump against memory limit, drop the highest-cost node from queue
 - ▶ Record in a node the cost of its best descendant node
 - ▶ Don't re-expand unless all other paths in memory are worse
- ▶ Complex search! – see R&N for details

Enough is as good as a feast.

—Joshua Sylvester, *Works* (1611).
